Graphics Computer System

Variable Density Disk Drive Controller

Reference Guide

Part No. 50-0010-002 Rev. E

This document describes the use of two types of Floppy Disk Drive Controllers in an 8510/a Graphics Computer System: a Variable Density Disk Drive Controller and a Single Density-only Disk Drive Controller. These modules control direct memory access (DMA) data transfer between system main memory and eight inch floppy diskette drives. Up to four drives, installed in 8510, 8512 and 8515 units, can be controlled. This hardware, in conjunction with appropriate software, supports the following formats: IBM 3740/1 single-sided, single density; 3740/1D single-sided, double density; IBM 3740/2D double-sided, double density. This hardware/software subsystem is completely compatible with original 8510/a Single Density, non-DMA configurations.

APPENDIX E. Variable Density Disk Drive Controller Reference Guide

E1. General Description

The 8510/a system utilizes eight inch magnetic floppy diskettes for mass storage. This document describes the use of either of two Disk Drive Controllers: a standard, Single Density-only Disk Drive Controller or an optional, Variable Density Disk Drive Controller. The Variable Density Disk Drive Controller, and its appropriate software handler, interfaces to single and dual head drives, and supports the IBM 3740/2D format for double density, modified frequency modulation (MFM) recording, as well as the IBM 3740 single density, frequency modulation (FM) format. As a result, the Variable Density Controller supports the transfer of data to and from diskettes in the following manner: single-sided, single-density (128 bytes per sector); single-sided, double-density (512 bytes per sector); and double-sided, double-density (512 bytes per sector). The Single Density-only Controller has all the attributes of the Variable Density Controller, however, it will only support the IBM 3740/1 single density (FM) format.

The hardware/software subsystem can control up to four drives whose diskettes have combinations of the previously described side and density options; the software handler recognizes the options when the diskette is inserted in a drive.

The Variable Density (and the Single Density-only) Controller provides, at the sector level, DMA data transfer between the main memory in the 8510 unit and up to four diskette drives. The Controller supports parallel-seek operation on all four drives; simultaneous multiple heads-down operation; multi-sector and multi-track data transfer; and diskette formatting for the soft-sectored recording mode. Data transfer rates are 250 K-bits per second for FM encoding and 500 K-bits per second for MFM encoding.

The Controllers also provide the electronics necessary to interface the diskette drives to the 8510/a system bus (identical to the LSI-11 Q-bus), plus record and recover information in single density formats (and double density formats - Variable Density Controller only).

The Controllers also contain a 255 word (16-bit) initial boot ROM. This ROM, and all applicable registers of the Controllers, are accessed via Bank 7 (I/O Page) of the LSI-11 address space.

Controller hardware consists of: a dual-width (8.9 in. W x 5.2 in. H) module, installed in a slot of the 8510 unit backplane, and an External Interface Board (EIB), installed on the rear surface of the 8510 unit, plus, interconnect cables. EIBs are also provided for the 8512 and 8515 units. DIP switches on the EIBs are used to assign a drive as unit 0,1,2, or 3.

Access Times	Single Head Drive	Dual Head Drive
Track to Track:	6 milliseconds	3 milliseconds
Head Settling Times:	8 milliseconds	15 milliseconds
Head Load Times:	35 milliseconds	35 milliseconds
Maximum Error Rates:	1 recoverable error per 10 **9 bits	1 non-recoverable error per 10 **12 bits

These error rates exclude external causes, such as diskette defects or contamination. A non-recoverable error is defined as an error that persists after the error recovery procedure is performed. The error recovery procedure consists of a fixed number (10) of retries to read the record in error.

E1.2 Media Considerations

By means of the information stored on Track 00 of all TERAk-supplied IBM-compatible diskettes, the user can access various formats, on different diskette media, simultaneously; this also allows various drive and media types to be used simultaneously.

Media originally formatted in single density, however, may not necessarily be reliable if re-formatted in double density. Double density formatting requires diskettes that are certified as reliable for double density recording.

E1.1 Diskette Formats & Drive Attributes

The following media formats are used by TERAk:

	Single-sided		Double-sided
	Single-density	Double-density	Double-density
Cylinders (Total)	77	77	77 **
Tracks (Total)	77	77 *	154 **
Index Track(s)	1	1	2
Sectors/Track	26	15	15
Data bytes/Sector	128	512*	512 **
Sectors/Diskette	2002	1166	2332
Data bytes/Diskette	256,256	587,008	1,173,344

* Track 00 is single-density, 128 bytes/sector, 26 sectors.

** Side 0, Cylinder 0, is single-density, 128 bytes/sector, 26 sectors.

** Side 1, Cylinder 0, is double-density, 256 bytes/sector, 26 sectors.

The drive assemblies used (single-head & dual-head) produce the following attributes:

Rotational Speed: 360 RPM +- 2.5 %
 Rotational Direction (as would be seen from the label side of a diskette): CW
 Tracks/Inch: 48
 Read/Write Track Width: 0.012 in.
 Inside Track Radius: 2.029 in.

Recording Density
 (inside track): 3200 bpi (single density)
 6400 bpi (double density, MFM)

Flux Density
 (inside track): 6400 fci (single density)
 6400 fci (double density, MFM)

Encoding Methods: FM (Single Density) MFM (Double Density)

Data Transfer Rates: 250 K-bits/S (Single Density, FM encoding)
 500 K-bits/S (Double Density, MFM encoding)

Average Latency: 83 milliseconds

Average Access Time: 260 milliseconds

E2. Controller Description

The Floppy Disk Controller module (FDC) is capable of transferring a minimum of one byte to a maximum of 16,384 bytes, in the Direct Memory Access (DMA) mode. Data anywhere in main memory can be transferred to the sectors of a diskette; conversely, data from any of the diskette sectors can be transferred to any of the locations in main memory. (Bank 7 is normally reserved for peripheral I/O device addresses.) The DMA data transfer is accomplished, with a minimum of processor overhead.

The FDC converts the data bytes from the main memory into a serial bit stream; this data stream is then interleaved with a serial clock bit stream. The resultant clock/data envelope is then recorded on a diskette as a series of flux changes. When a diskette is read, the flux changes are re-converted to a clock/data bit stream. A data recovery circuit separates the clock and data bit streams to recover the data bits. The FDC then converts the serial data bit stream into data bytes for storage in main memory.

The FDC will execute the following 15 instructions:

Read Data	Write Data	Sense Interrupt Status
Read ID	Write Deleted Data	Sense Drive Status
Read Deleted Data	Scan Equal	Seek
Read a Track	Scan High or Equal	Specify
Format a Track	Scan Low or Equal	Recalibrate (Restore to Track 00)

The FDC contains five Q-bus accessible registers, as shown in Figure E-1. The bits of the read-only FDC Status Register (QBCS) indicate data transfer direction, operating mode (DMA, non-DMA), data validity, FDC status and drive status. The Multi-Purpose Stack (QBMS) is used to store bytes in a certain sequence. These bytes specify the parameters of a diskette data transfer (i.e., physical location, data stream length, encoding method, etc.) and the type of operation to be performed.

As shown in Figure E-1, DMA is controlled by 3 Q-bus accessible registers. A 16-bit Bus Address Register (QBBA) is loaded with the starting address that specifies the beginning location, in main memory, for a data transfer. The lower 14 bits of a 16-bit Terminal Count Register (QBTC) are loaded with an ending, or terminal count value, that specifies the length of the data block to be transferred (the upper 2 bits specify read or write operation). When the DMA transfer commences, the starting address is put on the Q-bus and a DATI or DATO(B) operation occurs. The address is then incremented and the read or write operation is repeated. This sequence continues until the number of data transfers equals the value (plus one) loaded in the QBTC register. At that time, the transfer is completed.

The module also contains an 8-bit DMA Control/Status Register (QBDC). This register is used to enable the DMA and Floppy Disks; to enable the DMA interrupt; and to set the data direction (i.e., memory read or write).

E2.1 Processor Interface

The FDC can transfer a single byte (single DMA cycle), or multiple bytes (multiple-DMA cycles; i.e., DMA transfer). The addresses of the Q-bus accessible registers, are as follows:

Q-Bus Address (octal)	Mnemonic	Function
171000	QBCS	Floppy Disk Status Register
171002	QBMS	Multi-Purpose Stack
171012	QBDC	DMA Control/Status Register
171014	QBTC	Terminal Count Register
171016	QBBA	Bus Address Register
173000-173774		Initial bootstrap ROM

The FDC is capable of executing 15 instructions, as listed in Part E2 of this document. Descriptions of these instructions are contained in Part E4. Each instruction requires multiple-byte transfers to set up, execute, and complete an instruction. As a convenience, an instruction may be considered as consisting of three phases:

Command Phase: The FDC receives all information, required to perform a particular operation.

Execution Phase: The FDC performs the operation.

Results Phase: After completion of the operation, status and other housekeeping information is made available.

During the Execution phase, data bytes are transferred between the FDC and a drive.

The formats of QBCS and QBMS are shown in Figure E-2. One register monitors the FDC status, the other register location is actually a stack, used to store and retrieve data during the Command and Results phases of an instruction.

The formats of QBDC, QBTC and QBBA are shown in Figure E-3. These registers are used for DMA operations.

E2.1.1 Floppy Disk Status Register (QBCS)

During the Command and Result phases of an instruction, QBCS must be read before each byte is written into, or read from, the Multi-Purpose Stack (QBMS). This alternating QBCS-read/QBMS-write (during the Command phase) and QBCS-read/QBMS-read (during the Result phase) must occur before the FDC will execute the current instruction and accept a new instruction. During the Execution phase, QBCS need not be read.

QBCS is read from the lower byte of a Q-bus word at location 17100C, octal.

QBCS bits 0 through 3 reflect drive status; that is, whether or not a drive is busy (in Seek mode, to move the read/write head from track to track).

QBCS bit 4 indicates whether the FDC is busy with a read or a write operation.

QBCS bit 5 indicates the operating mode. This bit is set only during the Execution phase in the non-DMA mode; when bit 5 resets, the Execution phase has ended.

QBCS bit 6 indicates data transfer direction. A "0" means that data is being transferred from the Q-bus to the FDC; a "1" means that data is being transferred from the FDC to the Q-bus.

QBCS bit 7, when set, indicates that QBMS is ready to send or receive data.

E2.1.2 Multi-Purpose Stack (QBMS)

QBMS is a stack (of 8-bit registers) that is pushed and popped, respectively, during the Command and Result phases of an instruction. Each instruction requires that a specific sequence of bytes be loaded into, and read from, the stack. As shown in Figure E-2, a 1 or 2 byte command code (that specifies a particular instruction) must be loaded first, and then followed by 0 to 7 configuration bytes. After instruction execution, status bytes (whose bits specify any errors that had occurred during execution) and sector ID bytes (that either duplicate the sector ID bytes that were loaded during the Command phase or have been changed because of instruction termination) are returned to the stack. QBMS must be read (and interpreted) to proceed to a new instruction. The byte codes for QBMS are described in Part E3.

QBMS is written to, and read from, the lower byte of a Q-bus word at location 171002, octal.

E2.1.3 DMA Control/Status Register (QBDC)

QBDC must be programmed after QBTC and QBBA registers have been programmed. QBDC is cleared (reset) whenever a Reset instruction is executed, when the system is reset (boot switch depressed), or when power is cycled. Bit 0 of QBDC must be set to enable the DMA. When read, during a DMA cycle, QBDC bit 0 will be clear until the cycle is completed, at which time it will be set. When read after completion of a DMA cycle, QBDC bit 0 will be reset.

When set, during register programming, QBDC bit 3 will enable the Controller interrupt input upon completion of the DMA transfer.

QBDC bit 4 determines data direction during a DMA cycle; if programmed to "0", data will be transferred from memory to diskette.

QBDC bits 1, 2, 5, 6 and 7 must be programmed to the states shown in the QBDC bit map of Figure E-3 to prevent spurious operations.

QBDC is read from, and written to, the lower byte of a Q-bus word at location 171012, octal, and consumes a single DATI or DATOB bus cycle.

E2.1.4 Terminal Count Register (QBTC)

QBTC must be programmed with a number that is one less than the desired number of byte transfers. For instance, if "0" is loaded, a single DMA cycle would occur. A maximum of 16,384 bytes are allowed per DMA transfer.

The lower 14 bits of QBTC are used for the terminal count number; the upper 2 bits specify the data direction during a DMA operation. Only two combinatorial states are allowed for bits 6 & 7, as shown in the QBTC bit map of Figure E-3.

E2.1.5 Bus Address Register (QBBA)

QBBA must be programmed with the address of the first memory byte location to be accessed during the DMA operation. During the operation, the Controller will increment, (by one), the address put on the bus, until the desired number of byte locations (specified by the value loaded into the lower 14 bits of QBTC) have been accessed.

QBBA can be loaded with any starting address, however, Bank 7 (160000 to 177777, octal), of the LSI-11 address space, is generally reserved for I/O device addresses.

Note: QBTC and QBBA are both 16-bit registers that are written to the lower byte of a Q-bus word at respective locations 171014 and 171016, octal. Two DATOB bus cycles are required to load either register.

E3. Diskette & Track Geometry

The diskettes used with the Variable Density Controller can either be single or double density encoded, and, with the proper drive, can be single or double sided. Figure E-4 identifies the general characteristics of all diskettes used with the 8510/a system.

There are 77 concentric tracks on one surface (side) of a diskette. For double sided diskettes, pairs of tracks, on opposite sides, are termed cylinders. In comparison to single sided diskettes, data transfers to/from a double sided are faster, because the opposing tracks of a cylinder can be accessed, sequentially, without moving the read/write heads.

During diskette formatting, the tracks will be divided into 26 segments, or sectors, for single density recording, or 15 sectors, for double density recording. For all diskettes used with the 8510/a system, track 0, side 0, will always be FM encoded, with 26 sectors and 128 bytes/sector. This track specifies the recording density to be used for the other tracks; the Controller uses track 0, side 0 information (plus a drive status line signal) to determine the format for the diskette. The index hole on a single sided diskette is at a different location (with respect to the slot in the diskette's protective cover) when compared with a double sided diskette. The Controller uses the index hole position to differentiate between a single sided and a double sided diskette.

The gaps and fields of a sector are shown in Figure E-4. During a Format operation, these patterns are created by the system after it has detected the index hole. The system will format the track for single or double density recording. A track will be formatted in a single rotation of the diskette, beginning and ending with the index hole detection. As the track passes the read/write head(s), the R values (Sector No.s), written into the ID Field, need not be in sequential order. The C (Cylinder No.), H (Head No.) and N (Data Bytes/Sector No.) values are a function of the head position, diskette side and required density and cannot be randomly ordered. To read or write to any data field on a diskette, the user must load matching C,H,R,N values (Sector ID) into QBMS, prior to the execution of an instruction.

E4. Controller Instruction Set

The FDC has a repertoire of 15 instructions, as follows:

Read Data	Read a Track
Read ID	Read Deleted Data
Write Data	Write Deleted Data
Format a Track	Scan Equal
Recalibrate (Restore to Track 0)	Scan High or Equal
Seek	Scan Low or Equal
Specify	
Sense Interrupt Status	
Sense Drive Status	

The FDC requires multiple-byte transfers to execute the instructions. These bytes (and certain bits of some bytes) are described as follows.

E4.1 Byte Descriptions

- C; Cylinder No. : The current/selected cylinder number (0 to 76)
- H; Head No. : The selected read/write head (0 = Side 0; 1 = Side 1)
- R; Record No. : The sector (record) number (1 to 26, single density; 1 to 15, double density)
- N; Number : The number of data bytes/sector (0 for single density, 2 for double density) written into a sector.
- EOT; End Of Track: The final sector number (15 or 26) of a track.
- GPL; Gap Length: The Post-ID and Post-Data gap lengths; that is, the inter-record gaps. GPL is equated to a binary magnitude; see Table E3 for recommended values.
- DTL; Data Length: The number of data bytes written into or read from a sector when N = 0. If DTL defines a data length smaller than that which was defined by N when N was not zero, the read or write transfer will cease when the DTL value is reached. The FDC will continue to read or write (with zeroes) the remainder of the data field to perform the CRC function. When N is not zero, DTL must be set to all "1's" (i.e., FF, hex or 377, octal).

STP; Scan Track, Processor: During a Scan (High, Low, or Equal) instruction, the data bytes in a sector are compared with data bytes from the Q-bus. If STP = 1, the data bytes from contiguous sectors are compared. If STP = 2, data bytes from alternate sectors are compared.

ST0; Status 0: These are four registers that are read at the beginning of the Result phase of an instruction. The registers that are read depend on the particular instruction. The bits of the registers indicate what errors (if any) occurred during the instruction execution, and whether the instruction terminated normally or abnormally. See Tables E5 through E8 for a description of these registers.

ST1; Status 1:

ST2; Status 2:

ST3; Status 3:

SC; Sectors/Cylinder: During a Formatting instruction, SC determines the number of sectors to be written on a (track); (15 for double density; 26 for single density).

D; Data: During a Formatting instruction, D is the byte pattern that is written into the data fields to define the data field locations on a track. D can be any pattern.

PCN; Present Cylinder No. : PCN is read during the Result phase of a Sense Interrupt Status instruction and represents the present position of the read/write head(s) (i.e., at Cylinder 0 through 76).

NCN; New Cylinder No. : NCN is the cylinder number to which the read/write head(s) will move during a Seek instruction. NCN is loaded during the Command phase of Seek with value 0 through 76.

E4.2 Bit Descriptions

MT; Multi-Track: A command code bit in the Read, Write and Scan instructions. When MT = 1, data will be transferred to/from both tracks of a cylinder, starting at Sector 1, Side 0 and completing at Sector L (last sector) of the opposing track on Side 1, of a double sided diskette.

MF; FM or MFM Mode: A command code bit in the Read, Write, Scan and Format instructions. When MF = 0, the FM mode is selected; when MF = 1, the MFM mode is selected.

SK; Skip: A command code bit in the Read (except Read ID) and Scan instructions. When executing a Read Data or a Scan instruction, and SK = 1, the FDC will skip over, (not read), a sector that has a Deleted Data Address Mark (DDAM). The CRC bits of a skipped sector are not checked. At this time, if a Scan instruction is executing, the Control Mark (CM) bit of the ST 2 register is set, to indicate that a DDAM had been encountered.

When executing a Read Deleted Data instruction, and SK = 1, the FDC will skip over a sector that has a Data Address Mark.

When executing a Read a Track instruction, the SK bit is ignored.

When SK = 0, the FDC will read the field that would have been skipped over, and then terminate the instruction. At this time, the CM bit of ST 2 will be set.

HD; Head : A command code bit that indicates the selected head (0 = Head 0; 1 = Head 1). This bit must have the same value as H, the Head No. byte.

HLT; Head Load Time : Seven bits of a command code of the Specify instruction. HLT controls the head load time of a drive (defined as the interval between the assertion of a head load signal and the commencement of a read/write operation). HLT is programmable in 2 millisecond increments over the range 2 mS to 254 mS; it is equated to a binary magnitude: 2 mS = 01; 254 mS = FE,hex = 376,octal.

HUT; Head Unload Time: Four bits of a command code of the Specify instruction, programmable in 16 millisecond increments over the range 16 mS to 240 mS. (16 mS = 01; 240 mS = 0F,hex = 17,octal). HUT starts at the end of a R/W execution phase. Note: Hardware causes a head to remain loaded for 600 mS after the end of a R/W instruction execution phase.

SRT; Step Rate Time: Four bits of a command code of the Specify instruction. SRT controls the head stepping rate (defined as the time it takes to move from track to adjacent track). SRT is programmable in 1 millisecond increments; it is equated to a binary magnitude: 1 mS = F,hex = 17,octal; 16 mS = 0.

ND; Non-DMA Mode: A single bit of a command code of the Specify instruction. ND controls the operating mode of the Controller. When ND = 1, the non-DMA mode is selected; when ND = 0, the DMA mode is selected.

US1,US0; Unit Select: Two bits of a command code of every instruction (except Specify) that are used to select a drive.

US1	US0	Drive Selected
0	0	0
0	1	1
1	0	2
1	1	3

E4.3 Instruction Descriptions

The following listing describes the instructions and the order in which the byte and bit parameters of Parts E4.1 and E4.2 must be written to and read from the Multi-Purpose Stack (QBMS) to execute the instructions. (Note: An 'x' bit is a 'don't care' state.)

E4.3.1 Read Data Instruction

Nine bytes are written to QBMS to perform the Read Data instruction. After the instruction has been issued, the FDC loads the head (if it is in the unloaded state), waits the specified head settling time (defined in the Specify instruction) and begins reading ID Address Marks & ID Fields. When the current sector number (R), stored in an ID Register compares with the sector number read off the diskette track, the FDC will output data (from the data field), byte-by-byte, to the Q-bus.

After the current-sector data field is read, the Sector Number is incremented, by 1, and the data from the next sector is read and outputted to the Q-bus. This continuous-read is a 'Multi-Sector Read Operation'. The Read Data instruction may be terminated by the FDC reaching DMA Terminal Count (TC), (from QBTC). When the FDC reaches TC, the FDC will stop outputting data to the Q-bus, but will continue to read data from the current sector, check the CRC bytes, and then terminate the Read Data instruction at the end of the current sector.

The 'Multi-Track' function (MT bit) allows the FDC to read data from both tracks of a cylinder. For any cylinder, data will be transferred starting at Sector 1, Side 0 and completing at Sector L (last sector) of Side 1.

When $N = 0$, then DTL defines the data length which the FDC must treat as a sector. If DTL is smaller than the actual data length in a sector, the data beyond DTL is not sent to the Q-bus. The FDC will read the remaining sector data to perform the CRC check, and, depending on the manner of instruction termination, may perform a "Multi-Sector" Read operation. When N is non-zero, DTL has no significance, and must be set to FF,hex or 377,octal.

At the completion of the Read Data (or Write Data) instruction, a head is not unloaded until a 600 ms interval has elapsed. If the CPU issues another instruction before the head unloads, then the delay caused by the Head Load Time (HLT) interval may be eliminated for subsequent read/write operations.

If the Controller detects the diskette Index Hole twice, without finding the correct sector (as defined by R), then the FDC will set the ND flag in ST1, and terminate the instruction. ST0 bits 7 & 6, (Interrupt Code bits), will be toggled to 0 and 1, respectively, to flag an abnormal termination.

After reading the ID and Data Fields in each sector, the FDC checks the CRC bytes. If an incorrect CRC in the ID Field is detected, the DE (Data Error) flag in ST1 will be set. If an incorrect CRC is detected in the Data Field, the DD (Data Error in Data Field) flag in ST2 and the DE flag of ST1 will both be set. In both cases, the Read Data instruction will be terminated.

If the FDC reads a Deleted Data Address Mark (DDAM) off the diskette, and SK = 0, the Control Mark (CM) flag in ST2 will be set, and the Read Data instruction will be terminated after the sector data is read. If SK = 1, the FDC will skip over the sector with the Deleted Data Address Mark and read the next sector. The CRC bytes in the deleted data field are not checked when SK = 1.

During data transfers between the FDC and the Q-bus, the FDC must be serviced every 27 microseconds in the FM mode, and every 13 microseconds in the MFM mode, or the FDC will set the Over Run (OR) flag in ST1, and terminate the Read Data instruction.

If a Read (or a Write) instruction is terminated, the Sector ID information, during the Result phase, will be dependent upon the state of the MT bit and EOT byte loaded during the Command phase. The Sector ID information, (C, H, R, N), at termination, is shown in Table E1. The amount of data that can be transferred depends upon MT (Multi-Track), MF (Mode), and N (Number of Bytes/Sector). Table E2 lists the transfer capacity.

READ DATA

Phase	R/W	FDC Data Register Bits								Remarks
		7	6	5	4	3	2	1	0	
Command	W	MT	MF	SK	0	0	1	1	0	Command codes
	W	x	x	x	x	x	HD	US1	US0	
	W	-----C-----								Sector ID codes prior to instruction execution.

E4.3.2 Read Deleted Data Instruction

This instruction is the same as the Read Data instruction, except that when the FDC detects a Data Address Mark, at the beginning of a Data Field (and SK = 0), it will read all the data in the sector, set the CM (Control Mark) flag of ST2, and terminate the instruction. If SK = 1, then the FDC skips over the sector with the Data Address Mark and reads the next sector.

READ DELETED DATA

R	-----N-----								Sector ID codes after instruction execution.	

E4.3.3 Write Data Instruction

Nine bytes are written to the FDC Data Register to perform the Write Data instruction. After the instruction has been issued, the FDC loads the head (if it is in the unloaded state), waits the specified head settling time (defined in the Specify instruction), and begins reading ID fields. When the current sector number (R), stored in an ID Register, compares with the sector number read off the diskette track, the FDC will transfer data from the Q-bus to the diskette drive.

After writing data into the current sector, the Sector number is incremented, by 1, and the next data field is written onto the track. The FDC continues this 'Multi-Sector Write Operation' until a DMA Terminal Count (TC) is reached (from QBTC). When the DMA TC occurs, the FDC continues to write into the current sector; if the DMA TC is reached while a data field is being written, the FDC will write zeroes into the remainder of the field.

The FDC reads the ID field of each sector and checks the CRC bytes. If an incorrect CRC is detected, the FDC will set the Data Error (DE) flag of ST1, and terminate the Write Data instruction. If the FDC tries to access a sector beyond the final sector (as configured by SC during a Format a Track instruction), of a cylinder, the EN (End of Cylinder) flag bit, of ST1, will be set.

In the Write Data instruction, data transfers between the FDC and the Q-bus must occur every 31 microseconds in the FM mode, and every 15 microseconds in the MFM mode, or the FDC will set the Over Run (OR) flag in ST1, and terminate the instruction. STO bits 7 & 6 (Interrupt Code bits) will also be toggled to 0 and 1, respectively, to flag an abnormal termination.

The Write Data instruction operates in much the same manner as the Read Data instruction. The following items are the same:

1. Sector ID Information when the CPU terminates an instruction. (Refer to Table E1.)
2. Transfer Capacity (refer to Table E2).
3. Definition of DTL when N is and is not zero.
4. Head Load and Unload Time intervals.
5. ND (No Data) flag bit of ST1.

	R	-----N-----								

E4.3.5 Read A Track Instruction

This instruction is similar to the Read Data instruction, except that this is a continuous read operation, where the entire data field, from each of the sectors, is read. After the Index Hole is detected, the FDC starts reading all the data fields on the track, as continuous blocks of data. If the FDC finds an error in the ID or Data CRC bytes, it continues to read data from the track. The FDC compares the ID information read from each sector with a value stored in an ID Register; if the values do not match, the ND (No Data) flag bit of ST1 will be set. Multi-track and skip operations are not allowed with the Read A Track instruction.

This instruction terminates when the EOT number of sectors have been reached. If the FDC does not find an ID Address Mark on the diskette after the Index Hole has been detected, for the second time, then the MA (Missing Address Mark) flag bit in ST1 will be set, and the instruction will be terminated. ST0 bits 7 & 6 (Interrupt Code bits) will also be toggled to 0 & 1, respectively.

READ A TRACK

	R	-----R-----									
	R	-----N-----									

E4.3.6 Read ID Instruction

The Read ID instruction is used to give the present position of the read/write head. The FDC stores the values from the first ID Field it is able to read. If no proper ID Address Mark is found on the diskette, before the Index Hole is encountered for the second time, then the MA (Missing Address Mark) flag bit in ST1 is set; if no data is found, the ND (No Data) flag bit in ST1 is also set. The instruction is then terminated, and ST0 bits 7 & 6 (Interrupt Code bits), are also toggled to 0 & 1, respectively, to flag an abnormal termination.

READ ID

	R	-----H-----								
	R	-----R-----								
	R	-----N-----								

E4.3.7 Format A Track Instruction

The Format instruction allows an entire track to be formatted. After the Index Hole is detected, format data is written on the track: Gaps, Address Marks, ID Fields and Data Patterns, for single or double density encoding, are stored. The particular format to be written is controlled by the values programmed into: N (no. of bytes/sector), SC (sectors/cylinder), GPL (gap length of Post-ID & Post-Data gaps) and D (Data Pattern) byte. The Data Field is filled with the D byte, for definition. The ID Field for each sector is supplied from the Q-bus; that is, four requests, per sector, are made by the FDC for: C (Cylinder No.), H (Head No.), R (Sector No.) and N (No. of bytes/sector). This allows the diskette to be formatted with non-sequential sector numbers, if so desired.

After formatting each sector, the Q-bus is referenced for new values for C, H, R and N for each sector. The contents of the FDC R Register are incremented by one, after each sector is formatted, so that the R Register contains a value of R when it is read, during the Result phase. This incrementing & formatting continues until the FDC detects the Index Hole for the second time, and terminates the instruction. The effects that N, SC and GPL have on formatting are shown in Table E3.

FORMAT A TRACK

Phase	R/W	FDC Data Register Bits								Remarks

	R	-----H-----								
	R	-----R-----								
R	-----N-----									

E4.3.8 Scan Instructions

The Scan instructions allow data that is being read from a diskette to be compared against data that is on the Q-bus (in the DMA mode). The FDC compares the data on a byte-by-byte basis, and looks for a sector that meets the requirement of the Scan instruction (i.e. Data Equal; Data Equal or Low; Data Equal or High). One's complement arithmetic is used for the comparison (FF, hex = largest number; 00 = smallest number). After a whole sector of data is compared, if the conditions are not met, the sector number (R) is incremented by STP ($R + STP$ returned to R), and the Scan operation is continued. The operation continues until one of the following events occur: the conditions for Scan (Equal, Low or High) are met, the last sector on the track is reached (EOT), or the DMA TC (Terminal Count) is reached.

If the conditions for Scan are met, the FDC will set the SH (Scan Equal Hit) flag bit of ST2, and terminate the instruction. If the conditions for Scan are not met, between the starting sector (as specified by R) and the last sector (as specified by EOT), then the FDC will set the SN (Scan Not Satisfied) flag bit of ST2, and terminate the instruction. If the DMA TC is reached during the Scan operation, the FDC will complete the comparison of the current byte, and then terminate the instruction. Table E4 lists the states of SH and SN under various conditions of Scan.

If the FDC encounters a Deleted Data Address Mark on one of the sectors, and SK = 0, then this sector will be regarded as the last sector on the cylinder; the FDC will set the CM (Control Mark) flag bit of ST2, and terminate the instruction. If SK = 1 when the Deleted Data Address Mark is encountered, the FDC will skip over that sector and read the next sector; the FDC will also set the CM bit of ST2 to indicate that a Deleted Data Address Mark had been encountered.

When either the STP (scan contiguous sectors = 01; scan alternate sectors = 02) or the MT (access both tracks of a cylinder = 1) variables are programmed, it is necessary to remember that the last sector on the track must be read. For example, if STP = 02, and MT = 0, and if the sectors are numbered sequentially 1 through 26, and the Scan instruction is started at Sector 21, then the following will occur: Sectors 21, 23 and 25 will be read, Sector 26, (the last sector), will be skipped and the Index Hole will be encountered, thereby terminating the instruction, abnormally. If EOT had been set to 25, (instead of 26), or if the Scan had started at Sector 20, instead of 21, the instruction would have terminated normally.

During a Scan instruction, data is transmitted from the Q-bus and the diskette and compared in the FDC. The data bytes must arrive at the FDC within 27 microseconds (for FM mode) or 13 microseconds (for MFM mode), or the OR (Over Run) flag bit of ST1 will be set and the instruction will terminate abnormally (the Interrupt Code bits 7 & 6, of ST0 will be toggled to 0 & 1, respectively).

E4.3.9 Seek Instruction

The read/write heads of the drives are moved from cylinder to cylinder under control of the Seek instruction. The FDC compares the PCN (Present Cylinder Number) to the NCN (New Cylinder Number), and if there is a difference, steps to a new cylinder.

The rate at which steps occur is controlled by SRT (Stepping Rate Time), in the Specify instruction. After each step, NCN is compared to PCN; when NCN = PCN, the SE (Seek End) flag bit of ST0 will be set, and the instruction will be terminated.

During the Command phase of Seek, the FDC is in the FDC Busy state; during the Execution phase, it is in the Non-Busy state. Another Seek instruction can be issued while the FDC is in the Non-Busy state; in this manner, parallel Seek operations can be performed on up to 4 drives, simultaneously.

If a drive is in a Not-Ready state at the beginning of the Seek Execution phase, or during the Seek operation, the NR (Not Ready) flag bit of ST0 will be set, and the instruction will be terminated. The Interrupt Code bits, 7 & 6, of ST0, will be toggled to 0 & 1, respectively.

SEEK

Phase	R/W	FDC Data Register Bits								Remarks
		7	6	5	4	3	2	1	0	
Command	W	0	0	0	0	1	1	1	1	Command codes
	W	x	x	x	x	x	HD	US1	US0	
	W	-----NCN-----								
Execution		Head is positioned over the proper cylinder on the diskette.								

Note: Because Seek does not have a Result phase, a Sense Interrupt Status instruction must always be performed after a Seek instruction, to effectively terminate Seek.

E4.3.10 Recalibrate Instruction

The function of this instruction is to retract the read/write head of a drive to the Track 00 position. The FDC clears the contents of the PCN (Present Cylinder Number) counter, and checks the status of a Track 00 signal from the drive. As long as this Track 00 signal is low, Steps are issued to move the head. When the Track 00 signal goes high, (indicating that the head is at Track 00), the SE (Seek End) flag bit in ST 0 will be set and the instruction terminated.

If the Track 00 signal is still low after 77 Steps have been issued, the FDC will set the SE and EC (Equipment Check) flag bits of ST0, and terminate the instruction. The Interrupt Code bits of ST0, bits 7 & 6, will be toggled to 0 & 1, respectively.

The ability to do overlapping Recalibrate instructions to multiple drives, and the loss of a drive Ready signal, (as described in the Seek instruction), also applies to the Recalibrate instruction.

RECALIBRATE

Phase	R/W	FDC Data Register Bits								Remarks
		7	6	5	4	3	2	1	0	
Command	W	0	0	0	0	0	1	1	1	Command codes
	W	x	x	x	x	x	0	US1	US0	
Execution		Head retracted to Track 00.								

Note: Because Recalibrate does not have a Result phase, a Sense Interrupt Status instruction must be performed after a Recalibrate instruction to effectively terminate Recalibrate.

E4.3.11 Sense Drive Status Instruction

This instruction can be used to obtain the status of the drives. ST3 contains the drive Status information.

SENSE DRIVE STATUS

Phase	R/W	FDC Data Register Bits								Remarks
		7	6	5	4	3	2	1	0	
Command	W	0	0	0	0	0	1	0	0	Command codes
	W	x	x	x	x	x	HD	US1	US0	
Result	R	-----ST3-----								Drive status

E4.3.12 Sense Interrupt Status Instruction

An interrupt signal is generated, by the FDC, for one of the following reasons:

1. Upon entering the Result Phase of the following instructions:
 - A. Read Data
 - B. Read a Track
 - C. Read ID
 - D. Read Deleted Data
 - E. Write Data
 - F. Format a Track
 - G. Write Deleted Data
 - H. Scan (High, Low or Equal)
2. A drive changes its Ready state.
3. The end of a Seek or Recalibrate instruction.

Interrupts caused by 1 occur during normal command operations and are easily discerned. Interrupts caused by 2 & 3, however, can be uniquely identified by use of the Sense Interrupt instruction. When this instruction is issued, the cause of the interrupt will be identified, via bits 5, 6 and 7 of ST0, as follows:

Bit 7 (Interrupt Code)	Bit 6 (Seek End)	Bit 5	Cause of Interrupt
1	1	0	Ready line changed state, either polarity.
0	0	1	Normal termination of Seek or Recalibrate.
0	1	1	Abnormal termination of Seek or Recalibrate.

Note: Neither the Seek or the Recalibrate instructions have a Result phase; therefore, it is mandatory that the Sense Interrupt Status instruction be used, immediately afterwards, to effectively terminate Seek or Recalibrate, and to provide head position verification.

SENSE INTERRUPT STATUS

Phase	R/W	FDC Data Register Bits								Remarks
		7	6	5	4	3	2	1	0	
Command	W	0	0	0	0	1	0	0	0	Command code
Result	R	-----ST0-----								FDC Status at the end of seek-operation.
	R	-----PCN-----								

E4.3.13 Specify Instruction

The Specify instruction sets the initial values of three timers in the FDC: HLT (Head Load Time), HUT (Head Unload Time), and SRT (Step Rate Time). This instruction also determines the Controller operating mode via the ND (Non-DMA) bit. These time and control variables are described in Parts E4.1 & E4.2 of this document.

SPECIFY

Phase	R/W	FDC Data Register Bits								Remarks
		7	6	5	4	3	2	1	0	
Command	W	0	0	0	0	0	0	1	1	Command codes
	W	<-----SRT----->				<-----HUT----->				
	W	<-----HLT----->								

E4.4 Invalid Operation

If an invalid instruction (one not described in Part E4.3) is sent to the FDC, the FDC will terminate the instruction after Interrupt Code bits 7 & 6, of ST0, are toggled to 0 & 1, respectively. Bit 7 (QBMS Status) and bit 6 (Data Transfer Direction) of QBMS will both be set, indicating that the FDC is in a Result phase and that the contents of ST0 must be read. When ST0 is read, it will be found to contain 80 (hex), indicating that an invalid instruction was issued.

A Sense Interrupt instruction must be sent after a Seek or Recalibrate instruction, or else the FDC will interpret the next instruction to be an invalid one.

INVALID

Phase	R/W	FDC Data Register Bits								Remarks
		7	6	5	4	3	2	1	0

1	10	Sector 8, @ Side 1	C+1	LSB	R=01	NC

Note 1: NC = No Change; the same value as was loaded during the Command Phase.

Note 2: LSB (Least Significant Bit); the LSB of H is complemented.

Note 3: EOT is listed in octal; Sector is listed in decimal.

TABLE E1. ID Information When The CPU Terminates An Instruction

MT	MF	N	Maximum Transfer Capacity (Bytes/Sector)x(No. of Sectors)	Final Sector Read from Diskette
0	0	00	(128)x(26) = 3,328	26 @ Side 0 or
0	1	01	(256)x(26) = 6,656	26 @ Side 1
1	0	00	(128)x(52) = 6,656	26 @ Side 1
1	1	01	(256)x(52) = 13,312	
0	0	01	(256)x(15) = 3,840	15 @ Side 0 or
0	1	02	(512)x(15) = 7,680	15 @ Side 1
1	0	01	(256)x(30) = 7,680	15 @ Side 1
1	1	02	(512)x(30) = 15,360	
0	0	02	(512)x(8) = 4,096	8 @ Side 0 or
0	1	03	(1024)x(8) = 8,192	8 @ Side 1
1	0	02	(512)x(16) = 8,192	8 @ Side 1
1	1	03	(1024)x(16) = 16,384	

Table E2. Transfer Capacity

N	SC	GPL(1)	GPL(2)	Mode	Sector Size (Bytes/Sector)	Format
00	32	07	13	FM	128	IBM Diskette 1
01	17	16	52	FM	256	IBM Diskette 2
02	10	13	72	FM	512	
03	04	x	x	FM	1,024	
04	02	x	x	FM	2,048	
05	01	x	x	FM	4,096	
01	32	16	66	MFM	256	IBM Diskette 2D
02	17	13	124	MFM	512	
03	10	65	164	MFM	1,024	IBM Diskette 2D
04	04	x	x	MFM	2,048	
05	02	x	x	MFM	4,096	
06	01	x	x	MFM	8,192	

Note: The GPL(1) values are suggested for Read and Write instructions to avoid splice points between the Data Field and ID Field of contiguous sectors.

The GPL(2) values are suggested for the Format instruction.

The N, SC and GPL values are in hexadecimal.

The x values are to be determined by the user.

SC and GPL are listed in octal.

Table E3. Formatting Variables

Command	Status Register 2		Comments
	SN = Bit 2,	SH = Bit 3	
Scan Equal	0	1	Data(Drive)=Data(Q-bus)
	1	0	Data(Drive)not=Data(Q-bus)
Scan Low or Equal	0	1	Data(Drive)=Data(Q-bus)
	0	0	Data(Drive)<Data(Q-bus)
	1	0	Data(Drive)>Data(Q-bus)
Scan High or Equal	0	1	Data(Drive)=Data(Q-bus)
	0	0	Data(Drive)>Data(Q-bus)
	1	0	Data(Drive)<Data(Q-bus)

Table E4. SH & SN Status Bits

BIT 7, BIT 6 : INTERRUPT CODE (IC).

Bit 7 = 0: Normal termination of instruction (NT).
 Bit 6 = 0: Instruction was properly executed and completed.

Bit 7 = 0: Abnormal termination of instruction (AT).
 Bit 6 = 1: Execution was started, but not successfully completed.

Bit 7 = 1: Invalid instruction issued (IC). Instruction
 Bit 6 = 0: was issued, but never started.

Bit 7 = 1: Abnormal termination due to state change of a
 Bit 6 = 1: drive Ready signal, during instruction execution.

BIT 5 : SEEK END (SE).

When the FDC completes the SEEK instruction, this flag is set (1).

BIT 4 : EQUIPMENT CHECK (EC).

If the drive fails to reach Track 00 after 77 Steps (during the Recalibrate instruction), then this flag will be set (1).

BIT 3 : NOT READY (NR).

When a drive is in a Not-Ready state and a read/write instruction is issued, this flag will be set. If a read/write instruction is issued to Side 1 of a single-sided drive, this flag will be set.

Table E5. Status Register 0 Description

BIT 2 : HEAD ADDRESS (HD).

This flag is used to indicate the state of a head when an interrupt occurs. When set, the head is down.

BIT 1 : UNIT SELECT 1 (US1).

BIT 0 : UNIT SELECT 0 (US0).

These bits indicate the selected drive when an interrupt occurs:

Bit 1	Bit 0	Drive Selected
0	0	0
0	1	1
1	0	2
1	1	3

Table E5. (Cont.) Status Register 0 Description

BIT 7 : END OF CYLINDER (EN).

When the FDC tries to access a sector beyond the final sector of a cylinder, this bit will be set.

BIT 6 :

Not used; always low (0).

BIT 5 : DATA ERROR (DE).

When the FDC detects a CRC error in either an ID field or a Data field, this flag is set.

BIT 4 : OVER RUN (OR).

If the FDC is not serviced within a certain time, during data transfers, this flag is set. Refer to the Read and Write Data and the Scan instruction descriptions for the time intervals.

BIT 3 :

Not used, always low (0).

BIT 2 : NO DATA (ND).

During the execution of a READ DATA, WRITE DELETED DATA or SCAN instruction, if the FDC cannot find the Sector specified in an ID register, this flag will be set.

During the execution of a READ ID instruction, if the FDC cannot read the ID field without an error, this flag will be set.

Table E6. Status Register 1 Description

During the execution of a READ A TRACK instruction, if the FDC cannot find the starting sector, this flag will be set.

BIT 1 : NOT WRITABLE (NW).

During the execution of a WRITE DATA, WRITE DELETED DATA or FORMAT A TRACK instruction, if the FDC detects a Write Protect condition from a drive, this flag will be set.

BIT 0 : MISSING ADDRESS MARK (MA).

If the FDC cannot detect the ID Address Mark after encountering the Index Hole twice, this flag will be set.

If the FDC cannot detect the Data Address Mark or Deleted Data Address Mark, this flag will be set; at the same time, the MD bit (Missing Address Mark in Data Field) of ST2 will also be set.

Table E6. (Cont.) Status Register 1 Description

BIT 7 : Not used; always low.

BIT 6 : CONTROL MARK (CM).

During a READ DATA or a SCAN instruction execution, if the FDC encounters a sector with a Deleted Data Address Mark, this flag will be set.

BIT 5 : DATA ERROR IN DATA FIELD (DD).

If the FDC detects a CRC error in the data field, this flag will be set.

BIT 4 : WRONG CYLINDER (WC).

When the C (Cylinder Number) value written on the track differs from the value stored in an ID register, this flag will be set. When WC is set, ND of ST1 will also be set.

BIT 3 : SCAN EQUAL HIT (SH).

During the execution of a Scan instruction, if the condition "Equal" is met, this flag will be set.

BIT 2 : SCAN NOT SATISFIED (SN).

During the execution of a Scan instruction, if the desired condition, Equal, High, or Low, is not met, this flag will be set.

Table E7. Status Register 2 Description

BIT 1 : BAD CYLINDER (BC).

When the value of C (Cylinder Number) written on the track is FF,hex (377,octal), this flag will be set. Also, when the C (Cylinder Number) value written on the track differs from the value stored in an ID register, this flag will be set. When BC is set, ND of ST1 will also be set.

BIT 0 : MISSING ADDRESS MARK IN DATA FIELD (MD).

If the FDC cannot read a Data Address Mark or Deleted Data Address Mark, this flag will be set.

Table E7. (Cont.) Status Register 2 Description

BIT 7 : Not used. Always 0.

BIT 6 : WRITE PROTECTED (WP).

This bit indicates the Write Protected state of a drive. Write Protected = 1.

BIT 5 : READY (RY).

This bit indicates the Ready state of a drive. Ready = 1.

BIT 4 : TRACK 00 (T0).

This bit indicates whether a drive head is positioned over Track 00. Track 00 = 1.

BIT 3 : TWO SIDE (TS).

This bit indicates if a two-headed drive AND a two-sided diskette are in use. Two-Sided = 1.

BIT 2 : HEAD ADDRESS (HD).

This bit indicates the side selected for a two-headed drive. Side 1 Selected = 1.

BIT 1 : UNIT SELECT 1 (US1).

BIT 0 : UNIT SELECT 0 (US0).

These two bits indicate the drive unit selected.

US1	US0	DRIVE SELECTED
0	0	0
0	1	1
1	0	2
1	1	3

Table E8. Status Register 3 Description

E5. Boot ROM

The FDC contains a ROM bootstrap program. The function of the program is to read logical block 0, from the system disk in Unit 0, and transfer it to memory locations 0 through 777, octal. When the transfer is completed, LSI-11 CPU control is transferred to location 0, where the software bootstrap for the system resides, to complete the boot process for the operating system.

The ROM bootstrap begins at location 173000, (octal), in the I/O page of the LSI-11 address space and is 256 words in length. Whenever a Reset instruction is executed, or the system reset (boot switch depressed), or when power is cycled, CPU control is transferred to location 173000. The bootstrap program will then:

1. Suspend CPU interrupts.
2. Create a temporary stack beginning at location 17000, octal.
3. Relocate itself, beginning at 10000, octal.

Once relocated, the bootstrap programs the FDC to read Sector 7, Cylinder 0, Side 0, of the diskette in Unit 0. At byte locations 72 and 76, diskette attribute identifiers are stored, as per the IBM specification. When the locations have been examined, and the diskette attributes determined, the FDC is appropriately programmed.

If the FDC and the disk drive are capable of supporting these attributes, logical block 0, of the system disk, is read into memory. If errors occur during this transfer, the bootstrap will attempt retries to correct the transfer process. If the prescribed number of retries will not complete the transfer, the CPU will suspend operation by executing a branch-to-self instruction. At this time, CPU register R0 will contain the memory location of the FDC command sequence being processed at the time of the error. CPU register R1 contains the memory location of the FDC status returned during the command sequence.

There are several special attributes of the ROM bootstrap program. One is that the bootstrap program will wait until drive unit 0 becomes ready, meaning that a diskette need not be inserted in the drive at the beginning of the boot process. The program will wait indefinitely, until a diskette is inserted and the drive door closed. Another feature is that the ROM bootstrap contains a Read-Only-Handler, which is activated via the breakpoint (BPT) instruction. Activation of the bootstrap, and its relocation, will set up locations 14 and 16, octal, to utilize the Read-Only-Handler.

The argument sequence is as follows:

- R0 = Physical Track No. (0-76, decimal)
- R1 = Running word count
- R2 = Running buffer address
- R3 (high byte) = Head No. (Always 0 for single-sided drives)
- R3 (low byte) = Sector No. (1-26, decimal, for single-density)
(1-15, decimal, for double-density)

This routine may be used for diagnostic read, or tests.
